

Deep vein thrombosis of lower limbs in patients with COVID-19

Trombose venosa profunda de membros inferiores em pacientes com covid-19

Orlando Adas Saliba Júnior¹ , Ana Flávia de Jesus Alves² , Camila Matarazzo² , Gabriela Teixeira Gonçalves² , Marcone Lima Sobreira¹ 

Abstract

As knowledge has accumulated, COVID-19 has come to be considered a disease of the respiratory system that can also cause multisystemic involvement. This study analyzed the prevalence of deep venous thrombosis (DVT) in the lower limbs of patients with COVID-19 by conducting an integrative review of the literature published from 2019 to 2022. The procedures involved in article selection were identification of keywords, definition of the search strategy, consultation of databases, and exclusion of duplicate articles and others that did not meet the review objectives. Exclusion of articles was based on the following exclusion criteria: articles on arterial vascular complications involving the lower limbs, laboratory experiments, cases reports describing venous and arterial complications involving other sites, and articles unrelated to the outcome of interest: DVT. A total of 284 articles were identified, 42 of which were included. There was considerable variability in the prevalence of DVT among patients with COVID-19 (range: 0.43 to 60.87%). The findings suggest that occurrence of DVT in patients with COVID-19 is associated with disease severity.

Keywords: anticoagulant; SARS-CoV-2; thromboembolism.

Resumo

Com o avanço do conhecimento, a covid-19 passou a ser considerada uma doença do sistema respiratório, podendo ter comprometimento multisistêmico. Analisou-se a prevalência de trombose venosa profunda (TVP) em membros inferiores em pacientes acometidos pela covid-19 através de uma pesquisa de revisão integrativa, considerando o período de 2019 a 2022. Os procedimentos utilizados para a seleção dos artigos foram identificação das palavras-chave, elaboração da estratégia de busca, consulta em bases de dados e exclusão dos artigos em duplicata e outros. A exclusão foi feita com base nos seguintes critérios: artigos sobre complicações vasculares arteriais em membros inferiores, pesquisas laboratoriais, relatos de casos referentes a complicações venosas e arteriais em outros sítios e artigos não relacionados ao desfecho de TVP. Do total de 284 artigos, foram incluídos 42. Observou-se grande variabilidade na prevalência de TVP em pacientes com covid-19 (0,43 a 60,87%). Sugere-se que a ocorrência de TVP em pacientes com covid-19 está associada à gravidade desta doença.

Palavras-chave: anticoagulante; SARS-CoV-2; tromboembolia.

■ INTRODUCTION

Coronaviruses (CoVs) are single-stranded ribonucleic acid (RNA) viruses that cause diseases in humans and animals.¹ In December of 2019, a new coronavirus strain was identified in patients presenting with pneumonia of unknown etiology and was named severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) by the International Committee on Taxonomy of Viruses (ICTV).¹ The same month, the first case of coronavirus disease 2019 (COVID-19) was confirmed in the city of Wuhan, in China.² The disease caused a global outbreak that was designated as a pandemic by the World Health Organization (WHO) on March 11, 2020.³

This pandemic spread rapidly, with more than 199 million confirmed cases and more than 4 million deaths worldwide during 2021,⁴ demonstrating high rates of contagion, morbidity, mortality, and lethality, provoking a major overload of health care systems.⁵

Transmission of COVID-19 occurs person-to-person by direct contact, by aerial transmission in aerosols, and during medical procedures.⁶ The incubation period of SARS-CoV-2 can be considered as from 2 to 14 days, with a mean period of 5 days,⁷ and it is diagnosed by testing nasopharyngeal swab samples with reverse transcriptase followed by polymerase chain reaction (RT-PCR).⁸

Around 80% of confirmed cases of COVID-19 are asymptomatic or mildly symptomatic;⁹ 15% progress to a more severe form; and 5% develop acute respiratory distress syndrome (ARDS) and require ventilatory support.⁷

Patients considered to have mild to moderate severity exhibit the following clinical manifestations: fever (88.7%), coughing (67.8%), tiredness (38.1%), productive expectoration (33.4%), dyspnea (18.7%), sore throat (13.9%), and headache (13.6%).¹

Severe infection is characterized by uncontrolled multisystemic inflammatory and immune response, with cardiovascular, respiratory, neurological, intestinal, hepatic, pancreatic, renal, cutaneous, and hematological involvement. This response is mediated by direct viral action, with endothelial dysfunction, inflammation, and thrombosis of the microcirculation of organs,¹⁰ and may induce sepsis, ARDS, bilateral interstitial pneumonia, multiple organ failure, and disseminated intravascular coagulation (DIC), and can lead to fatal outcomes.¹¹ The activation of blood coagulation provokes a prothrombotic state with significant elevation of fibrin, of fibrin degradation products (including D-dimer [DD]) and fibrinogen. The resulting state is known as COVID-19 associated coagulopathy (CAC). The pathophysiology of CAC includes cytokine storm, causing activation of endothelial

cells and pulmonary microvasculature injury, causing local microthrombosis, and a hypercoagulable state that can result in thrombosis of large vessels.²

From this perspective, the procoagulatory nature of COVID-19, combined with other risk factors, such as immobility, mechanical ventilation, and infection, predisposes patients to thromboembolic complications,⁷ such as deep venous thrombosis (DVT), pulmonary embolism (PE), arterial thrombosis, pulmonary thrombosis (PT),¹² unusual thrombosis of central lines or arterial catheters, and premature thromboses of extrarenal hemodialysis filters and extracorporeal membrane oxygenation (ECMO) cannulae.⁷

Considering the importance of the vascular involvement related to COVID-19 and the need for data to support decision making on the most effective forms of thromboprophylaxis, it is essential to discuss the impact of these complications and the different treatment approaches, justifying a wide-ranging review of the literature.

In view of the above, the objective of this study was to analyze the prevalence of DVT in the lower limbs of patients with COVID-19.

■ METHODS

This is an integrative review of the literature on COVID-19-related DVT in lower limbs, written up in accordance with the PRISMA protocol.¹³

The procedures employed to identify and select scientific output were based on consultations of the SciELO, PubMed, Cochrane, Scopus, Web of Science, and LILACS databases, considering publications from December 2019, when the pandemic started, to September 2022.

Relevant keywords were selected and the following search strategy was defined: COVID19 OR COVID-19 Viral Disease OR 2019-nCoV Disease OR Coronavirus 2019 Disease OR 2019-nCoV Coronavirus Disease OR Coronavirus-19 Disease OR Novel Coronavirus 2019 Disease OR COVID-19 Virus Disease OR Wuhan Coronavirus Pneumonia Epidemic OR Wuhan 2019-2020 Coronavirus Pneumonia Epidemic OR Coronavirus from Wuhan Pneumonia Epidemic OR Coronavirus from Wuhan 2019-2020 Pneumonia Epidemic OR Novel Coronavirus 2019-2020 Pneumonia Epidemic OR Wuhan Coronavirus Epidemic OR Coronavirus from Wuhan Epidemic OR Novel Coronavirus 2019 Epidemic OR 2019-nCoV Epidemic OR Wuhan Coronavirus Epidemic OR Coronavirus from Wuhan Epidemic OR Novel Coronavirus 2019 Epidemic OR Wuhan Coronavirus Pneumonia Fever OR COVID-19 Viral Infection OR Infection by the 2019-nCoV Coronavirus OR Infection by the Wuhan Coronavirus OR Infection by the SARS-CoV-2 OR 2019-nCoV

Infection OR 2019-nCoV Coronavirus Infection OR Wuhan Coronavirus Infection OR Novel Coronavirus 2019 Infection OR SARS Coronavirus 2 Infection OR SARS-CoV-2 Infection OR COVID-19 Virus Infection OR SARS-CoV-2 Infections OR COVID-19 Pandemic OR COVID-19 Pandemics OR Wuhan Seafood Market Pneumonia OR Wuhan Coronavirus Pneumonia OR Novel Coronavirus 2019-2020 Pneumonia OR Wuhan Coronavirus Outbreak OR 2019-2020 Chinese Pneumonia Outbreak OR Pneumonia Outbreak in China 2019-2020 OR 2019-nCoV Coronavirus Outbreak OR Wuhan Coronavirus Outbreak OR Wuhan Coronavirus 2019-2020 Outbreak OR Novel Coronavirus 2019 Outbreak OR 2019-nCoV Outbreak OR 2019-nCoV Coronavirus Outbreak OR Wuhan Coronavirus Outbreak OR Wuhan Coronavirus 2019-2020 Outbreak OR Novel Coronavirus 2019 Outbreak OR COVID-19 Virosis) AND (Deep Venous Thrombosis lower limbs OR Deep Venous Thrombosis lower limb OR Deep Vein Thrombosis lower limbs OR Deep Vein Thrombosis lower limb OR Thrombosis of lower limbs deep veins OR Thrombosis of lower limb deep veins OR Deep Vein Thrombosis lower extremities OR Deep Vein Thrombosis lower extremity).

The review included cross-sectional, case-control, and cohort studies that were directly related to the subject of interest. The first step in analysis of the articles was reading the titles and abstracts to classify them by study type and eliminate duplicated publications. The full texts of articles were then read to identify the characteristics, objectives, and results of each study. Data were extracted from each article

and input to a dedicated spreadsheet containing title, authors, year of publication, country in which the study was conducted, periodical, objective, type of study, sample, tests used for diagnosis, main results, and evidence level. An analysis was conducted to determine the degree of evidence of each article using the SORT (Strength of Recommendation Taxonomy) protocol. This classification stratifies evidence levels as: A) consistent and good quality patient-oriented evidence; B) inconsistent or limited quality patient-oriented evidence; or C) consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.

The review included articles related to the primary outcome of interest - symptomatic and asymptomatic DVT - and also cases diagnosed incidentally or systematically in the lower limbs of patients with confirmed COVID-19. Case reports and articles on arterial and venous vascular complications located in other anatomic sites were excluded. A total of 284 articles were identified, 42 of which were analyzed.

Figure 1 illustrates the procedures employed and the process for selection of articles from the databases.

RESULTS

Table 1 lists the data extracted from each of the 42 scientific articles selected for the review, including title, authors, year of publication, country in which the study was conducted, periodical, objective, study type, sample, tests used for diagnosis of DVT, and main results on disease prevalence.

41	Incidence and risk factors of deep vein thrombosis in hospitalized COVID-19 patients	Yuet al. ⁵⁰	2020	China	Clinical and Applied Thrombosis/Hemostasis	To evaluate the incidence rate and risk factors of deep venous thrombosis in patients with COVID-19.	Retrospective observational study	142 patients	Lower limb ultrasound with venous compression maneuver	50/142 patients (35.21%)	C
42	Deep vein thrombosis in hospitalized patients with COVID-19 in Wuhan, China: prevalence, risk factors, and outcome	Zhang et al. ⁵¹	2020	China	Circulation	To investigate deep venous thrombosis in patients hospitalized with COVID-19.	Cross-sectional observational study	143 patients	Lower limb venous ultrasonography	66/143 patients (46.15%)	C

The studies included (total n = 42) were conducted in Italy (n = 12), the United States (n = 8), France (n = 6), China (n = 5), Spain (n = 4), Brazil (n = 2), Argentina (n = 1), Croatia (n = 1), Egypt (n = 1), Sweden (n = 1), and Switzerland (n = 1). It was observed that the majority of the articles were cohort studies. Ultrasound was the supplementary test most often used to diagnose DVT in the lower limbs. There was major variability in the results for prevalence (range: 0.43 to 60.87%). The majority of articles were classified at evidence level A (n = 19).

■ DISCUSSION

This integrative review found that many different studies have been conducted in different parts of the world to investigate the signs and symptoms of COVID-19 and its systemic complications, such as DVT in the lower limbs. Clinical and epidemiological data are essential to guide planning and implementation of provision of health care for patients with these diseases.

It was observed that the majority of these studies were conducted in countries in Europe and America and just one study was conducted in Africa. In view of this, it is clearly important to conduct studies with different populations, considering the diversity of ethnicities, cultures, and social and economic conditions, with the objective of better understanding the multisystemic characteristics of the disease and identifying possible factors that could be associated with occurrence of DVT in the lower limbs of patients with COVID-19.

This review found that the incidence of cases of DVT in the lower limbs of patients with COVID-19 was investigated in different population groups, with mild, moderate, and severe forms of COVID-19, and it is possible that these factors have influenced the variability in the data reported by the studies analyzed.

A study conducted at the Wuhan Union Hospital, in China, with 88 patients admitted with confirmed COVID-19 pneumonia, 31 of which were critical cases, 33 severe cases, and 24 mild cases, identified DVT in the lower limbs of 19 patients (21.59%), 12 in critical patients and 7 in severe cases. This therefore suggests that occurrence of DVT in patients with COVID-19 may be related to disease severity, since it is more frequent in patients admitted to intensive care units in respiratory distress with respiratory rate ≥ 30 breaths/minute; peripheral oxy-hemoglobin saturation $\leq 93\%$ at rest; ratio of partial pressure of oxygen/fraction of inspired oxygen ≤ 300 mmHg; respiratory failure requiring mechanical ventilation; shock; or failure of other organs.^{16,50}

It is important to point out that, although the possible mechanisms and factors related to thromboembolic changes found in patients with COVID-19 have not been completely elucidated, the literature has demonstrated that formation of proinflammatory cytokines, induction of procoagulatory factors, and hemodynamic changes that predispose to ischemia and thrombosis can contribute to development of DVT in the lower limbs of these patients. Furthermore, changes that can be detected with laboratory tests, such as lymphopenia, neutrophilia, elevated prothrombin time, and elevated DD, have been observed in patients who develop venous thromboembolism.⁵

Recent studies have shown that patients hospitalized for COVID-19 are at high risk of development of thromboembolic events, and, consequently, there was a massive increase in requests for computed tomography and color Doppler ultrasonography (CDUS), with the objective of identifying cases of PE and DVT in these patients. The present review found that CDUS was the diagnostic method most used to identify DVT in the lower limbs of patients with COVID-19. Early diagnosis of DVT in the lower limbs of patients with COVID-19 is of fundamental importance for good prognosis. It should be stressed that examinations to investigate vascular changes are important regardless of the presence of signs or symptoms of DVT, especially in patients with severe cases of COVID-19, admitted to intensive care units, and/or on ventilatory support, with the purpose of diagnosis and monitoring of the problem, considering that the prevalence of DVT in lower limbs was higher in more severe cases and in the presence of immobilization.⁵⁰

Analysis of the treatments employed for management of DVT in the lower limbs of patients with COVID-19 suggests that early administration of prophylactic anticoagulant is beneficial to the prognosis of critical patients with COVID-19 pneumonia and will probably reduce the rates of thromboembolic events. However, there are inconsistencies in the literature.^{14,28,30,41,44,45}

The studies included in this review describe patients with COVID-19 of varying degrees of severity and from different population groups. The lack of additional detailed information about the health conditions of these patients was a factor that made in-depth analysis of these issues difficult, which can be considered a limitation of the study. Moreover, the analysis conducted in this review should be updated constantly, considering that different periods of time since the disease emerged may yield different findings.

It is clear that further studies are needed to confirm the applicability and effectiveness in specific population groups of the diagnostic methods and treatments used to treat DVT in the lower limbs of patients with COVID-19. The disease's extreme transmissibility and lethality meant that scientific efforts and resources were initially directed towards discovering preventative methods, with emphasis on development of vaccines for SARS-CoV-2, while the disease's multisystemic characteristics are now being better understood.

CONCLUSIONS

There was major variability in the prevalence of DVT in patients with COVID-19 and DVT in the lower limbs appears to be associated with more severe cases of COVID-19, such as in patients admitted to intensive care units with respiratory distress with respiratory rate ≥ 30 breaths/minute; peripheral oxy-hemoglobin saturation $\leq 93\%$ at rest; ratio of partial pressure of oxygen/fraction of inspired oxygen ≤ 300 mmHg; respiratory failure requiring mechanical ventilation; shock; or failure of other organs.
